

# Search for a Spanish Partner for a Bilateral R&D Project

Organization	
Date of Request:	11/11/2025
Company name:	Faculty of Dentistry, Alexandria University, Alexandria, Egypt
Contact person and title/ designation:	Professor Ahmed Samir Bakry; Professor of Operative Dentistry, Faculty of Dentistry, Alexandria University Egypt.
E-mail:	drahmedbakry@gmail.com
Phone number:	00201204742178
Mobile number:	00201204741916
Website:	https://scholar.google.com/citations?user=D72sjYAAAAAJ&hl=en

SECTION 1: Entity launching the partner search (Please give brief / to the point explanations. For more explanation on any point below, you may add a short paragraph as an annexure, with this document.)		
Sector	Education and Research in the Field of Dentistry.	
Entity mission or core functions	Education, Research and Development of innovative dental materials.	
Date of establishment	1970	
Ownership (if public and traded, add stock exchange and ticker symbol)	Egyptian Minister of Higher education.	
Total number of employees	5000	
Number of employees in R&D	Approximately 500 master and Ph.D. Research candidates	
Key products sold or services provided	Ph.D. and Master degrees in various fields of Dentistry.	
Entity core technical competences		
Key R&D programs and activities		
Examples of accomplishments	The research group applying has obtained 9 USA patents and more than 100 published research work.	
Company strategic orientation		

SECTION 2: Spanish Company Profile (Please provide a brief summary of the prospective partner company or organization. This summary may address some or all of the points below)		
Profile of ideal technology partner	Spanish Dental materials manufacturer whose products are approved for sale in the European Union territory.	
Core technological competencies and expertise	Manufacture of light curing dental adhesives and dental composite.	
Other essential qualifications (e.g.: ownership, track records etc.)		
If you have a list of companies with whom you are in contact or interested in contacting, please provide contact details	Kuss Dental S.L. Calle Isabel Colbrand 10, Nave 95 – 28050 – Madrid · Spain +34 917 362 317 +34 917 362 318 +34 608 578 686 info@kuss-dental.com	
If you are interested in collaboration: please specify details and other important information you want to share with a potential company	Our project aims at developing the manufacturing of dental adhesives and dental composites in Egypt. Our Egyptian pharmaceutical company partner wish to collaborate with a Spanish dental material manufacturer to produce an innovative bioactive dental adhesive resin and composite material (Which are USA patented and tested).	
Interested areas of collaboration	Manufacturing dental adhesives and Dental Composites	
Specific R&D contribution you are seeking/offering	We wish to collaborate with a Spanish dental manufacturer capable of manufacturing of dental adhesives commercially.	

Signature Name: Professor Ahmed Samir Bakry

Date: 11/11/2025

## Innovative borate Bioactive Dental materials for solving dental problems.

## Abstract

Dental caries was classified by the World Health organization as one of the most prevalent diseases in the world that is affecting 60-90% of school children and the vast majority of adults worldwide [1].

Minimal intervention concept includes early caries detection and risk assessment; remineralization of demineralised enamel and dentine; optimal caries preventive measures; minimally invasive operative interventions; and repair rather than replacement of restorations [2, 3] [4]. The most popular remineralizing agents used worldwide are mainly composed of high fluoride concentration agents or agents highly rich in calcium and phosphate [5].

The 45S5 bioglass is a bioactive glass that was introduced 50 years ago as a biocompatible material that revolutionized the treatment of commuted fractures and decreased significantly the body rejection of various implants in different parts of the body[6]. The therapeutic effect of 45S5 bioglass in the treatment of various vital boney defects was attributed to its unique property of forming a hydroxyapatite rich layer capable of bonding chemically to the hydroxyapatite crystals of bone[6]. In 2008, 45S5 was suggested to be used as a potent dentin desensitizing agents[7]. Our research team demonstrated the remineralization potential of the 45S5 bioglass under conditions simulating the clinical situation of the early development of dental enamel and dentin caries which is one of the major problems faced by the dental specialists worldwide [8-18].

Our research team has obtained multiple patents and published research work which introduced a new type of bioactive borate glass that has unique bioactive action (Capable of completely transforming into hydroxyapatite) and may have an antibacterial effect. Our research team suggested the possibility of adding this bioactive glass to currently available dental materials which may significantly improve its longevity [19] inside oral cavity and provide beneficial features which were not available in the currently available dental materials. Moreover, our innovative borate bioactive material can fortify currently available toothpastes to be applied on sound enamel in high caries risk patients or on dentin hypersensitivity cases to act as a protective layer capable of resisting the bacterial Biofilm acidic attack, and thus may play a role in decreasing the prevalence of caries.

This research project will examine the possibility of adding the borate bioactive glass to various resin blends to optimize the physical and the chemical properties of the resulting adhesive restorations which will pave the road for the commercialization of these materials.

# 10<sup>th</sup> EGYPTIAN-SPANISH JOINT CALL FOR R&D&I PROJECTS 2025

# STDF-CDTI CALL FOR PROPOSALS UNDER THE EGYPTIAN-SPANISH INNOVATION PROGRAMME (ESIP)

On 30<sup>th</sup> of June, 2016, a Joint Program for Cooperation was established by The Science, Technology, and Innovation Funding Authority (STDF) and the CDTI, E.P.E. (CDTI), to promote and fund market-driven research and technology development as well as to encourage partnerships and business-led R&D&I collaborative projects between entities from both countries. Within this program, CDTI and STDF agreed to launch joint calls for proposals.

This call for proposals aims to launch ambitious joint R&D projects of a high international standard between Egyptian and Spanish organizations. Potential projects will be funded by STDF in Egypt and CDTI in Spain.

## **CALL GUIDELINES:**

## 1) NODAL IMPLEMENTING AGENCIES

The Science, Technology, and Innovation Funding Authority, Ministry of Higher Education and Scientific Research, Government of Egypt, and the CDTI, E.P.E., Ministry of Science, Innovation and Universities, Government of Spain, are the nodal implementing agencies from the Egyptian and Spanish sides, respectively.

The Science, Technology, and Innovation Funding Authority is the nodal agency for the promotion of research, development, and innovation in the valued areas of Egypt's long-term competitiveness and development strategy. STDF funds and supports affiliated Egyptian universities and research organisations (collaboration permitted with other entities).

The CDTI is a Public Entity under the Ministry of Science, Innovation and Universities, Government of Spain, which fosters the technological development and innovation of Spanish Companies.

## 2) THEMATIC AREAS

This Call for proposals is open to collaborative R&D projects in the following areas/sectors:

## 1. Agriculture and Sustainable Food Production

- Climatic and extra-climatic factors affecting sustainable crop production
- Improvement of productivity and quality of livestock, aquaculture and fisheries
- Innovative solutions for combatting emerging infectious livestock diseases
- Agricultural waste management and biofuel production
- Advanced trends to improve plant and livestock productivity
- · Food processing, safety, and food security

## 2. Sustainable water management

- Water management and treatment
- Water desalination
- Water sanitation technology

## 3. Affordable & Inclusive Healthcare

- Cancer and stem cells
- Chronic diseases
- Geriatric medicine

## 4. Renewable Energy

- · New trends in renewable energy
- Advances in energy storage systems
- · Biofuel/biogas production

## 5. Environment sector

- Sanitation
- Waste treatment

## 6. Construction

- Advanced construction technology and materials
- Hybrid Concrete Construction (prefabrication plus in-situ)
- Energy efficiency of residential and commercial buildings
- Applications of informatics to construction
- Advanced construction management and methods

## 7. Transportation sector

- Railways infrastructure
- Railways management

## 8. Tourism and Antiquities sector

Tourism industry and management of tourist places

## 9. Strategic Industries sector

- Pharmaceutical sector
- Electric car sector
- Manufacturing industries sector: textile, clothing, paper, wood, petroleum materials, chemicals, plastics, metallurgy and electronics sector
- · Computer Hardware, Machinery and Electrical Appliance sector

## 3) TYPE OF PROPOSALS

Industry-driven and market-oriented R&D projects, as well as joint technological cooperation projects between industrial partners (start-ups, SMEs, and large companies) and Universities or Research Centers in Egypt, and industrial partners (start-ups, SMEs, and large companies) in Spain, consisting in the development or substantial improvement of new products, processes or services, will be considered.

Duration of projects: up to 2 years.

The proposals have to cover the thematic areas of agricultural and sustainable production, sustainable water management, affordable and inclusive healthcare, renewable energy, environment sector, construction, transportation sector, tourism and antiquities sector, and strategic industries sector to enhance bi-regional cooperation and develop new partnerships as well as strengthen existing ones.

## **TIMETABLE**

- Launch of Call for Proposals: 3<sup>rd</sup> of September 2025.
- Deadline for Submission of completed applications: 3<sup>rd</sup> of December 2025. 24:00 Cairo time.
- Eligibility feedback to applicants: 19<sup>th</sup> of December 2025.
- Label concession (estimated): September 2026.

### 5) WHO CAN APPLY?

Minimum eligibility criteria: The project partners should include at least one qualified researcher from Egypt (Ph.D. holder, affiliated to an Egyptian university or research institution), with an Egyptian industrial partner (with or without R&D units), and one qualified partner from Spain (1 company from Spain with or without an R&D department).

## **Eligible Spanish Applicants**

Spanish consortia should include at least one company. Participation of research institutes/universities and other organizations is welcome as self-funded participants or subcontractors.

## **Eligible Egyptian Applicants**

Eligible Egyptian consortia should include a partner (the Egyptian applicant) who is a Ph.D. holder, affiliated to an Egyptian University or research Institution. Collaboration with other entities such as companies, governmental partners, other research centres, technological centres, universities, and other R&D-performing organisations is permitted under STDF's regulations.

Only projects with an industrial or governmental partner from the Egyptian side will be funded. Consortia with industrial or governmental partners having R&D units will have a higher priority.

Egyptian applicants should submit a business and financial plan to manage the IPR for the Egyptian side. According to Egyptian laws, the IPR belongs to the funding agency (the STDF), unless the industrial or governmental partners share in the project funding. In this case, the IPR for the Egyptian side will be shared between the STDF and the project partners according to their financial contribution.

## 6) HOW TO APPLY?

## First stage - Common International phase:

Identical joint R&D&I proposals must be submitted to CDTI and STDF, starting the 3<sup>rd</sup> of September 2025 to the 3<sup>rd</sup> of December 2025, in order to consider the eligibility. Unilaterally submitted proposals shall not be considered.

Egyptian Applicants should upload an electronic version (soft copy) of the proposal on the STDF's website (<a href="http://www.stdf.eg">http://www.stdf.eg</a>).

In Spain, the participants will have to submit a formal R&D international project application through CDTI's website <a href="https://sede.cdti.gob.es/">https://sede.cdti.gob.es/</a>

## Documents:

Egyptian and Spanish co-applicants must elaborate a single project proposal (Annex 1 – Joint Application Form). The Joint Application Form must emphasize how the proposed collaboration adds value, the main technology highlights and innovations, as well as the activities to be developed by the Parties involved, underlining the collaborative work being carried out on each side, their expertise, etc.

A plagiarism check will be applied to all proposals. Accordingly, the proposal must be submitted in a readable PDF format (i.e. not scanned), to facilitate plagiarism checks.

Please note that this **Joint Application Form** must be sealed and signed by all co-applicants at the end of the document, explicitly indicating the name of the authorized signatory and his/her designation in the organization. Any other relevant information not explicitly mentioned on the form, and that the applicants consider relevant, may be included as Annexes.

- In addition to the Joint Application form, co-applicants have to submit the following documents to STDF and CDTI as relevant appendices:
  - Consortium Agreement in English (Annex 2) whereby the co-applicants should agree upon the ownership, access rights and exploitation of intellectual property generated during the co-operation, to be submitted to

CDTI and STDF. The Consortium Agreement needs to be sealed and signed by all co-applicants.

- Any additional specific documents required by STDF and CDTI, as per their respective guidelines and internal rules.
- Additional specific documents required by CDTI: In the case of Spanish applicants, for certain specific types of financing, it will be necessary to present the documents specified in the regulations applicable to the requested aid.
- Egyptian applicants shall submit applications as per STDF guidelines. Supportive documents should be submitted from the Egyptian PI, including the Acknowledgment Form (Annex 3) and Endorsement Letters (Annexes 4 and 5). Supportive documents should be stamped and signed by the PI's institution.

## Second Stage - National level

Only those proposals which have positive eligibility by CDTI and STDF will be able to submit the individual R&D&I proposal in its own language established by each agency.

- The funding Proposal in English language required by STDF: The proposal and the other documents in English language for the STDF must be submitted on its due date established by STDF.
- The funding Proposal in Spanish is required by CDTI. Only industrial partners, individually, are able to submit the funding proposal and other required documents through the electronic services at <a href="Sede Electrónica del CDTI">Sede Electrónica del CDTI</a>. Application must be submitted within 20 working days after receiving the notification of eligibility.

The complete details of the Call are available on STDF's and CDTI's websites: <a href="http://www.stdf.eq">http://www.stdf.eq</a> and <a href="http://www.stdf.eq">http://www.stdf.eq</a> and <a href="http://www.stdf.eq">http://www.stdf.eq</a> and <a href="http://www.stdf.eq">http://www.stdf.eq</a> and <a href="http://www.stdf.eq">http://www.stdf.eq</a>

Applicants are recommended to contact the nodal representatives at their national funding organizations whose contact details are given below:

## Egyptian side (STDF)

Mrs. Mariam Abdelghany Science, Technology & Innovation Funding Authority - STDF 101 Kasr Al-Ainy St., Cairo, Egypt E-mail: mariam.abdelghany@stdf.eq

## 7) ELIGIBLE COSTS AND FUNDING

The project must clearly specify the costs of each and all activities pertaining to the project and specify the costs to be respectively borne by the Spanish and Egyptian partners. The cost of the Egyptian and Spanish partners must be eligible under the laws that may be applicable in each country and under the internal regulations of STDF and CDTI, respectively.

The funding conditions from STDF and CDTI are set in €. Budgets must be expressed in €.

None of the countries' budget (namely the budget of its entities participating in the proposal) can have more than 70% of the global budget. Besides, STDF cannot fund more than 50 % of the global Budget. This information will be also included in point 1.8 of the Application Form document.

- CDTI can only provide funding to Spanish companies subject to budget availability.
   The Spanish company will be funded according to the 'International Technological Cooperation Projects'-PCTIs conditions identified on CDTI's website.
- STDF will fund each project with 75,000 Euros 150,000 Euros, to be disbursed in the local currency (Egyptian Pounds) according to the exchange rate at the time of contracting. As per STDF's regulations, eligible project expenditures will include:
  - Salaries for the team (not to exceed 25% or up to 2,000,000 LE, whichever is less)
  - Equipment, Expendable supplies, and Materials
  - Travel (not to exceed 20% or up to 1,000,000 LE, whichever is less)
  - Publication costs and workshops
  - Indirect costs [not to exceed 20% of the (Total Direct Cost Total Equipment Cost) or up to150,000 LE, whichever is less].

## 8) REVIEW PROCESS AND EVALUATION

All received proposals are peer-reviewed and processed independently by both sides. After having received the recommendations of the respective evaluation panels, STDF and CDTI will jointly arrive at a mutual understanding on the projects to be funded.

## 9) EVALUATION CRITERIA

The joint projects must meet the general requirements of the funding organizations. The evaluation criteria are the following:

- Crucial Criteria
  - Financial capacity of Partner
  - Formal Agreement between Partners

- Basic Assessment Criteria
  - Partnership and Partners
    - o Well balanced partnership
    - Added Value through co-operation
    - Technology Capacity of all Partners
    - Managerial Capacity of all Partners
  - Project Structure
    - Methodology and Planning Approach
    - Milestones and deliverables
    - Cost, financing structure, and Financing commitment of each Partner
- Technology and Innovation
  - Technological Advances
    - Degree of technological maturity and risk
    - Technological Achievements
  - Innovation
    - o Degree of innovation
    - Geographical / sector impact
- Market and Competitiveness
  - Market and profitability
    - Market size
    - Market access and risk
    - Return on investment
  - Competitive advantages
    - Strategic importance of the project
    - o Enhanced capabilities and visibility

## **10) FUNDING DECISIONS**

STDF and CDTI will, after having formed their mutual understanding on the projects to be funded, make their funding decisions according to their normal procedures and rules and on a non-exchange of funds basis. CDTI and STDF will inform the beneficiaries about the funding decisions according to their normal practice.

## 11) REPORTING AND PROJECT OUTPUT

Funding granted by STDF and CDTI will be governed by the general terms and conditions of each funding organization, respectively. Both parties will carry out an international follow-up until the completion of the projects and inform the counterpart about the success or failure of the international cooperation at the end of the project.

If required, each participant should submit financial and technical reports to their national funding organisations, according to national regulations. The progress and final results of each individual contract/letter of grant will be monitored by the respective national funding organisations.

## (57) ABSTRACT

A bioactive borate glass adhesive system is described for its composition and use in adhering a plurality of dental restorative components onto a tooth surface. The adhesive system comprises silanated borate bioactive glass particles and a biocompatible resin blend. The bioactive adhesive system functions as a non-degradable, permanent adhesive in tooth restoration in the presence of saliva. In addition, the bioactive borate adhesive system may be used for re-mineralization, de-sensitization and self-healing of dentin and enamel by releasing and depositing calcium and phosphate ions onto the exposed and damaged tooth surface.

### (57) ABSTRACT

A dental filling material comprising bioactive borate glass particles, wherein the particles are at a concentration of 40-60 wt %, a co-monomer resin blend, a photoinitiator, and a co-initiator is provided. Method for applying the dental filling material to a tooth structure are also provided. The temporary filling material re-mineralizes the tooth structure and is removed after 1-7 days for the placement of a permanent filling material.

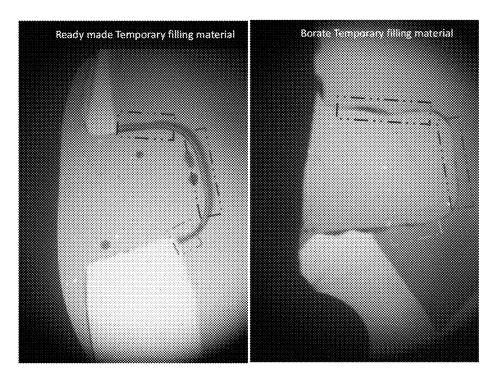

FIG. 1A FIG. 1B

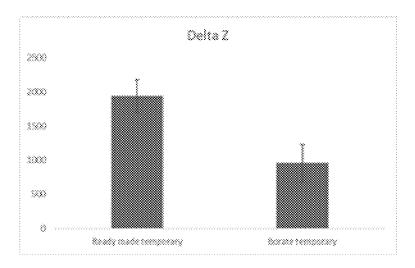

FIG. 1C

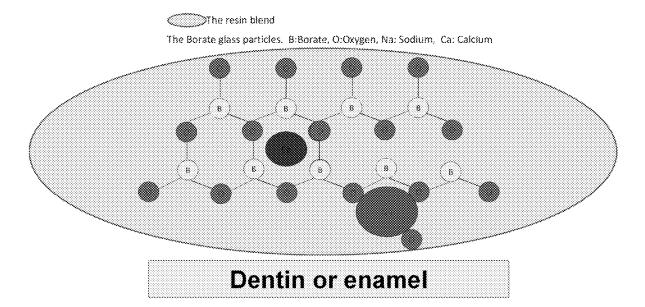

FIG. 2A

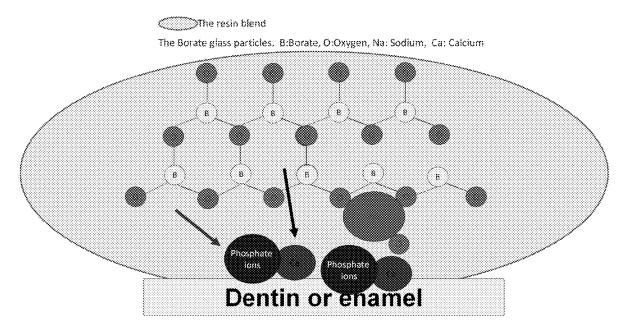

FIG. 2B

# BIOACTIVE DENTAL TEMPORARY FILLING MATERIAL

### FIELD OF THE INVENTION

The invention is generally related to a self-adhesive temporary dental filling material containing bioactive borate glass particles in a co-monomer resin blend. The material may be used to fill a cavity after caries removal and serves to re-mineralize the tooth structure until it is removed and a 10 permanent filling material is applied.

## BACKGROUND OF THE INVENTION

Dental caries is among the most prevalent diseases in the 15 world (Bakry et al. 2014a). Dental resins and ceramics revolutionized the dental restorative options for patients worldwide by replacing the metallic dental restorations with various types of highly esthetic restorations based on a resinous composite. One of the major advantages of the 20 introduction of resinous composite restorations is its ability to bond to tooth structures with minimum retentive mechanical features of the prepared cavities conducted by the dentist. This unique feature allowed conservation of much of the tooth structure and increased the longevity of teeth in the 25 oral cavities of dental patients. The increased awareness for the importance of conserving as much tooth structure as possible during cavity preparation led to the introduction of the Minimal Intervention Concept (Frencken et al. 2012) that advocated all means to conserve teeth structure and 30 remineralizing any teeth lesions rather than surgically removing all teeth lesions regardless of its depth.

The acceptance of this concept led to change of the caries removal technique done by dentists as only the removal of the caries zones infected by bacteria was advocated, while 35 the zones that are demineralized by bacteria were preserved. However, when applying the resinous restorative materials on demineralized enamel or dentin tissues, the bond strength between them may be jeopardized which may be attributed to increased inter crystalline porosity of the hypomineralized 40 dental tissues, moisture retention within the inter-rods spaces, (William et al. 2006) and higher protein contents (William et al. 2006). So, the idea of remineralizing the demineralized tooth structure proved its efficacy in improving the bond strength between dental tissues and the restor- 45 ative resin materials (Bakry and Abbassy 2019), but the need of having the remineralizing agents in direct contact with the dental hard tissues for at least 24 hours remained a problem that needs solving. It is a common practice among dentists to place temporary restorations after finishing their cavity 50 preparations for at least 24 hours prior to placing their permanent restorations in next appointment, however, most of the temporary filling materials available in the market do not possess any remineralizing capacity for tooth structure.

The first type of bioactive glasses was introduced by 55 Professor Larry Hench in the 1960s and it was called the 45S5 bioglass (Hench 1991), which had the ability to form a hydroxyapatite rich layer capable of interacting with hard and soft tissues (Hench 1991). Previously, the bioactive glasses were used mainly in the field of orthopedics and 60 periodontology (Hench 1991; Hulbert S. F. 1987; Yamamuro T. 1990). The majority of the literature focused on the use of various compositions of bioactive glasses on bone (Bellucci et al. 2015; Bretcanu et al. 2009; Hu et al. 2009; Sahli et al. 2015) and soft tissues (Mao et al. 2015).

U.S. Pat. No. 10,624,994 (incorporated herein by reference) describes the use of a mixture of borate glass and a

2

phosphoric acid aqueous solution for the re-mineralization of enamel and as a dentin desisitizing agent, however, the aforementioned borate-phosphoric paste physical properties did not enable it to exert a clinically acceptable bonding property to bond composite filling material to enamel and dentin

## **SUMMARY**

Described herein is a bioactive temporary filling material that can be light cured, thus gaining immediate good mechanical properties, and is able to self-adhere to tooth structures without need for retentive aids.

An aspect of the disclosure provides a dental filling material comprising bioactive borate glass particles, wherein the particles are at a concentration of 40-60 wt %, a co-monomer resin blend, a photoinitiator, and a co-initiator. In some embodiments, a composition of the particles comprises 20-30 mol % Na<sub>2</sub>O, 20-30 mol % CaO, 1-5 mol %  $P_2O_5$ , and 40-50 mol %  $B_2O_3$ . In some embodiments, the resin blend comprises 30-40 wt % bisphenol A diglycidyl ether dimethacrylate (Bis-GMA). In some embodiments, the resin blend further comprises 10-20 wt % ethylene glycol dimethacrylate. In some embodiments, the photoinitiator is 0.05-0.2 wt % camphorquinone. In some embodiments, the co-initiator is 0.05-0.25 wt % ethyl N,N-dimethyl-4-aminobenzoate (EDMAB). In some embodiments, the material does not include phosphoric acid.

Another aspect of the disclosure provides a method for applying a dental filling to a tooth structure, comprising applying a dental filling material as described herein onto an exposed surface of a tooth and curing with light for an effective amount of time to harden the dental filling material. In some embodiments, the method further comprises removing the dental filling material from the tooth and applying a second dental filling material to the tooth. In some embodiments, the removing step is performed 1-7 days after the curing step. In some embodiments, the dental filling material releases calcium and phosphate ions to a hybrid layer when exposed to saliva. In some embodiments, the calcium and phosphate ions form a hydroxyapatite layer on a surface of dentin or enamel to re-mineralize the tooth.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A-C. Transmicroradiography experimental results. The temporary borate filling material (B) increased the mineral content at the cervical, pulpal and occlusal walls as compared to the ready-made temporary filling material (A). (C) The graph shows that the mineral loss decreased significantly p<0.05 when the borate temporary material was applied.

FIGS. 2A-B. Mechanism of the borate glass bonding treatment for dentin or enamel. (A) The borate glass particles embedded in the resin blend are applied to a dentin or enamel surface. (B) Calcium and phosphate ions released from the borate particles re-mineralize the dentin or enamel structures.

## DETAILED DESCRIPTION

Embodiments of the disclosure provide bioactive borate glass embedded in a resin blend that is capable of light curing thus obtaining immediate good mechanical properties. This temporary filling material is capable of adhering to tooth structure without need for retentive features. Moreover, this material may act as a potent re-mineralizing agent

for demineralized enamel white spot lesions associated with orthodontic treatment or with Molar Incisor Hypomineralization cases

As used herein, the term "bioactive" refers to a material that generates a positive reaction when in certain biological 5 environments and/or is subjected to a chemical or physical process that modifies the material's surface to form a desired substrate, in this case, for re-mineralization of dentin or enamel. Bioactive materials referred to herein are those with the ability of promoting phosphate mineral (i.e. hydroxyapatite) precipitation when immersed in phosphate-rich physiological medium (i.e. saliva). A bioactive material may also bind chemically with the surrounding bone or promote cell attachment or growth.

The term "glass" refers to a non-crystalline amorphous 15 solid having a breaking stress or surface compressive stress of 10 MPa-30 GPa at 20-40° C. Glass may or may not comprise silica (SiO<sub>2</sub>).

A "composite" refers to a solid material comprising more than one phase, structure, and/or compound.

In some embodiments, a bioactive borate glass comprises 30-60 mol %, preferably 35-55 mol %, more preferably 40-50 mol %  $B_2O_3$  (borate); 10-40 mol %, preferably 15-35 mol %, more preferably 20-30 mol % CaO; 10-40 mol %, preferably 15-35 mol %, more preferably 20-30 mol % 25  $Na_2O$ ; and 0.5-15 mol %, preferably 1-10 mol %, more preferably 1-5 mol %  $P_2O_5$ , where each mol % is in mole percents based on 100 mol % of the total composition of the borate bioactive glass which may be generated by a plurality of methods.

In a preferred embodiment, a conventional "melt quench" synthesis method may be used. In this method, the borate bioactive glass may have a Ca:P molar ratio of 1:1-17:1, preferably 2:1-10:1, more preferably 3:1-7:1. The borate bioactive glass may be made by melting glass precursors 35 such as carbonate salts, a phosphate salt, and boric acid (H<sub>3</sub>BO<sub>4</sub>) to form a glass. For example, the glass precursors, Na<sub>2</sub>CO<sub>3</sub>, CaCO<sub>3</sub>, H<sub>3</sub>BO<sub>4</sub>, NaH<sub>2</sub>PO<sub>4</sub>, as well as others as needed, may be ground into powders using a mortar and pestle, or obtained as powders, and mixed to yield 20-40 g 40 of final glass product. These powders may comprise particles having largest dimensions of 0.1-200 µm, preferably 0.5-100 μm, more preferably 1-50 μm. Preferably the mixed powder contains a ratio of the glass precursors to generate an equivalent mole percent as mentioned above. In other 45 embodiments, different glass precursors may be used to ultimately produce equivalent compositions after melting to form a glass. For instance, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> may be used in place of H<sub>3</sub>BO<sub>4</sub>, or Na<sub>2</sub>HPO<sub>4</sub> may be used in place of NaH<sub>2</sub>PO<sub>4</sub>. A person having ordinary skill in the art may be able to 50 determine a practical amount of glass precursors to form a glass having one of the aforementioned compositions.

Some examples of preparation and treatment steps of borate glass particles are herein incorporated by reference (U.S. Pat. No. 10,624,994 to Bakry). According to some 55 preferred embodiments, the powder mixture of glass precursors may be heated in a furnace, oven, kiln, air, Pt or Pt alloy crucible, then allowed to cool to room temperature and molded, crushed or ground to produce borate bioactive glass in the form of particles. In one embodiment, the powder mixture heated in a Pt crucible was quenched on a stainless-steel plate and pressed with another plate to obtain glass plate pieces with a thickness of 0.2-1 mm. In this embodiment, the glass particles were obtained in a porcelain mortar and further pulverized using agate planetary mill. Alternatively, a sol-gel method may be used to form the borate bioactive glass particles at lower temperatures. In addition,

4

the particles from different glass powders may be mixed and re-melted to form the bioactive glass particles.

In one embodiment, the borate bioactive glass particles may further comprise Ca(PO<sub>3</sub>)<sub>2</sub>, K<sub>2</sub>O, TiO<sub>2</sub>, CaF<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub>, CuO, SrO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Ga<sub>2</sub>O<sub>3</sub>, and/or ZnO, preferably TiO<sub>2</sub>, CaF<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub>, CuO, SrO, and/or ZnO, more preferably TiO<sub>2</sub>, SrO, and/or ZnO. Preferably, these compounds or precursors to these compounds are added to the powder mixture before the heating and melting. It is possible that one or more of Ca(PO<sub>3</sub>)<sub>2</sub>, K<sub>2</sub>O, TiO<sub>2</sub>, CaF<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub>, CuO, SrO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Ga<sub>2</sub>O<sub>3</sub>, and/or ZnO may be present in the bioactive borate glass, each at a weight percentage of 0-10 wt %, preferably 0.2-8 wt %, more preferably 0.4-6 wt %, even more preferably 0.5-3 wt %, relative to a total weight of the borate bioactive glass particles.

In a preferred embodiment, the borate glass product may be further treated with 3-6 vol % of g-methacryl-oxypropyltrimethoxysilane (g-MPS) in acetone with 0.1-0.5 vol % of water in order to cover the exposed hydroxyl groups of the borate glass particles and to coat the hydroxyls with silanelike molecules, thus making the surface chemically inert. In this embodiment, the borate bioactive glass particles are substantially free of Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub> or MgO. The term "substantially free of Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub> or MgO" refers to the condition in which the SiO<sub>2</sub> content, the Al<sub>2</sub>O<sub>3</sub> content, the MgO content, or all three are less than 0.5 wt %, preferably less than 0.2 wt %, more preferably less than 0.1 wt % with respect to the total weight of the borate bioactive glass. In some embodiments, borate bioactive glass being completely free of Si, Al or Mg may not be possible due to sample impurities or environmental contamination. In an alternative embodiment, the borate bioactive glass particles may comprise particles clustered together as agglomerates.

The borate bioactive glass particles disclosed herein may have overall shapes that are spherical, ellipsoidal, oblong, ovoidal, angular, rectangular, prismoidal, or some other shape. The borate bioactive glass particles may have sharp, acute, pointed, or jagged edges. In one embodiment, the borate bioactive glass particles have longest dimensions or diameters of 1-200  $\mu m$ , preferably 2-100  $\mu m$ , more preferably 5-40  $\mu m$ . Small bioactive glass (i.e. the particles with diameters of 1-5  $\mu m$  or 1-3  $\mu m$ ) may be used to facilitate mixing and/or to more quickly dissolve in any application solutions known in the art. Further, the present disclosure relates to borate bioactive glass particles that are not in phosphoric acid solution or are free of any other acidic solutions.

In some embodiments, the borate bioactive glass particles may have submicron diameters, such as 100-900 nm, preferably 200-800 nm. As the average diameter of dentinal tubules is about 1 µm, particles with submicron diameters may be able to enter a dentinal tubule. The ratio of the longest dimension to the shortest dimension of the borate bioactive glass particles may be 1:1-1:10, preferably 1:1.05-1:5, more preferably 1:1.1-1:2. In one embodiment, the borate bioactive glass particles have longest dimensions within 75-125% of the average particle longest dimension, preferably within 80-120%. In one embodiment, the borate bioactive particles may have surface area to volume ratios of 15 nm<sup>-1</sup>-50  $\mu$ m<sup>-1</sup>, preferably 0.3  $\mu$ m<sup>-1</sup>-10  $\mu$ m<sup>-1</sup> more preferably 0.8  $\mu$ m<sup>-1</sup>-5  $\mu$ m<sup>-1</sup> and bulk densities of 1-8 g/cm<sup>3</sup>, preferably 1.2-5 g/cm<sup>3</sup>, more preferably 1.5-4 g/cm<sup>3</sup>. In some embodiments, the borate bioactive glass particles may have pores with diameters of 1-12 nm, preferably 1.5-8 nm, more preferably 1.8-5 nm, which may provide higher surface area to volume ratios.

02 11,002,012

To manufacture the borate bioactive glass temporary filling material, a resin blend is added and mixed with the borate bioactive glass particles described above. In one embodiment, the (optionally silanated) borate glass is incorporated with a co-monomeric resin blend at a concentration 5 of, preferably 40-60 wt %, e.g. 45-55 wt %, more preferably about 50 wt %, relative to a total weight of the borate bioactive filling material. In some embodiments, the borate glass does not exceed 50 wt % such that it has low enough physical and mechanical properties to facilitate its removal 10 after a few days of application to the tooth.

5

In one embodiment, the resin blend comprises 30-40 wt %, e.g. about 34.75 wt %, of bisphenol A diglycidyl ether dimethacrylate (Bis-GMA) or other dimethacrylate monomers, such as, 10-20 wt % of ethylene glycol dimethacrylate. 15 Other examples of non-degradable polymers that may be added to the material include polymethylmethacrylate, polyhydroxyethylmethacrylate (HEMA), urethane dimethacrylate (UDMA), triethylene glycol dimethacrylate (TEGDMA).

The contact surface between the bioactive borate material and the treated tooth are hardened or cured by a plurality of adhering methods (e.g. light-activated or chemical polymerization) and by applying the required method for an effective time to cure and/or form a hydroxyapatite layer on 25 the surface of the dentin or enamel to re-mineralize the tooth. In a preferred embodiment, the effective time of light curing is about 10-40 seconds. The effective time of light curing may be adjusted accordingly based on the volume, material and/or intended purposes of the bioactive system.

As used herein, "hardening" or "curing" a composition are used interchangeably and refer to polymerization and/or crosslinking reactions including, for example, photopolymerization reactions and chemical polymerization techniques.

In certain embodiments, the filling material is photopolymerizable, i.e., the hardenable component is photopolymerizable and the hardener includes a photoinitiator (or photoinitiator system), in which irradiation with actinic radiation initiates the polymerization (or hardening) of the 40 material. Some exemplary photoinitiators that may be incorporated into the material include camphorquinone (CQ), 2,4,6-trimethylbenzoyl-diphenylphosphine oxide (TPO), bisacylphosphine oxide (BAPO), benzophenone (BP), 9,10phenanthrenequinone (PQ), 1-phenyl-1,2 propanedione 45 (PPD), 9-(2,4,6-trimethylbenzoyl)-9-oxytho-9-phosphafuluorene (TMBOPF), 9-(p-toluyl)-9-oxytho-9-phosphafuluorene (TOPF), benzoyltrimethylgermane (BTMGe), dibenzoyldiethylgermane (DBDEGe), ivocerin-dibenzoyl germanium (IVO) and 7-ethoxy-4-methylcouramrin-3-yl) 50 phenyliodo-nium hexafluoroantimonate (P3C-SB). In some embodiments, the photoinitiator is present in an amount of 0.05-0.2 wt %. The most preferred photoinitiator, in this embodiment, is camphorquinone, which can work by itself but becomes more efficient with further incorporation of 55 co-initiators. The most commonly used co-initiators are ethyl-4-(dimethylamino(benzoate (EDMAB), NN-dimethyl-p-toluidine (DMPT), and 2(NN-dimethylamino)ethyl methacrylate (DMAEMA). In some embodiments, the coinitiator is present in an amount of 0.05-0.25 wt %. Alter- 60 natively, the compositions of the filling material are chemically polymerizable, i.e., the compositions contain a chemically polymerizable component and a chemical initiator that can polymerize, cure, or otherwise harden the composition without dependence on irradiation with actinic 65 radiation. Such chemically polymerizable compositions are sometimes referred to as "self-cure" compositions and may

include glass ionomer cements, resin-modified glass ionomer cements, redox cure systems, and combinations thereof.

Additionally, medicaments or other therapeutic substances can be optionally added to the filling material. Examples include, but are not limited to, fluoride sources such as tertbutyl ammonium tetrafluoroborate, whitening agents, anticaries agents, calcium sources, phosphorus sources, re-mineralizing agents (calcium phosphate compounds), enzymes, breath fresheners, anesthetics, clotting agents, acid neutralizers, chemotherapeutic agents, immune response modifiers, antimicrobial agents, antifungal agents, desensitizers, and the like. Combinations of any of the above additives may also be employed. Furthermore, the filling material, especially at the manufacturing steps of borate bioactive glass particles, may further comprise a salt such as KNO3, NaF, SnF2, SrCl2, and/or CaCl2, preferably NaF, SnF<sub>2</sub>, and/or CaCl<sub>2</sub>, more preferably NaF and/or SnF<sub>2</sub>. These salts may provide beneficial effects to dentin and enamel re-mineralization; for instance, fluoride from NaF or 20 SnF<sub>2</sub> may intercalate and strengthen a hydroxyapatite lattice within or on an enamel or dentin layer. The salt may be present at a weight percentage of 0.1-10 wt %, preferably 0.2-5 wt %, more preferably 0.25-4 wt % relative to a total weight of the borate bioactive glass filling material.

Previously available temporary dental filling materials are inert materials whose only function is to fill the dental cavity prepared by the dentists and prevent the impaction of food in these cavities for a scheduled next appointment with the dentist. During this period (at least 24 hours and may be extended to be 10 days or more), the tooth enamel and dentin surfaces and internal structures do not benefit from the chemical components of the temporary filling material. Moreover, the wide spread of Molar Incisor Hypomineralization syndrome (which involves the presence of white spot demineralization regions on the enamel of molars and incisors in children) without clearly determining the cause or effective treatment of this syndrome is one of the major challenges faced by dentists worldwide. Due to the dynamic nature of the oral cavity, most of the re-mineralizing agents will be dissolved and washed out by the action of saliva. The demineralization of tooth structure and the subsequent caries destruction to the dental tissues leads to the early loss of teeth with subsequent increase of burden on health service organizations worldwide.

The borate temporary filling material described herein has the ability to release calcium and phosphate ions to be applied on enamel and dentin hypomineralized surfaces and adhere to these surfaces for at least 24 hours releasing a high amount of calcium and phosphate to the demineralized enamel and dentin tissues. The temporary filling material enables the transfer of large quantities of calcium and phosphate ions from the temporary filling material to the internal structures of the dental enamel and dentin rendering these surfaces more resistant to caries and more suitable to receive the final resinous restorations. Moreover, the borate temporary filling material can improve the color of the demineralized enamel white spot lesions by re-mineralizing these enamel lesions. The borate glass has excellent adhesive properties that enables it to adhere effectively to the enamel and dentin walls and at the same time attain acceptable mechanical properties due to its light cured matrix. The borate glass temporary filling material, when exposed to the oral saliva, starts slow releasing the borate glass particles in the resin matrix to the surrounding dental hard tissue and starts forming calcium-phosphate compounds on top of the dental enamel and dentin and eventually these compounds will dissolve by the salivary action and penetrate the struc-

6

ture of the enamel and dentin causing their re-mineralization by the calcium and phosphate compounds. The ions released from the borate glass will not be washed out by the action of the saliva but will be in intimate contact with the enamel and dentin surfaces due to the adhesive properties of the 5 temporary filling material. This adhesive property aids the borate temporary filling in releasing all its rich components of calcium and phosphate to the tooth structure causing the improvement of the physical and mechanical properties of tooth structures. The borate glass released calcium and 10 phosphate compounds eventually crystallize to form hydroxyapatite which is the same chemical structure of the dental enamel and dentin and thus a chemical bond may be formed between the hydroxyapatite formed by the borate glass and the biologic hydroxyapatite of the tooth structure. 15

Embodiments of the disclosure include methods of applying the dental filling to a tooth structure including steps of applying the dental filling material onto an exposed surface of a tooth and curing with light for an effective amount of time to harden the dental filling material. The material may 20 be used to temporarily fill a cavity created after removal of caries. The material is self-adhesive and no additional adhesive material or binder needs to be added to the composition or the surface of the tooth. After 1-20 days, e.g. 1-10 days, e.g. 1-7 days, the temporary filling material is removed and 25 a permanent dental filling material, e.g. a resinous restoration, is applied to the tooth. The permanent filling material can remain in the tooth for several years. The mode of treatment by the borate temporary filling material improves the characteristic of the tooth structures and leads to the 30 resistance of these treated tooth structures to caries and erosive attacks leading to the increased longevity of the teeth.

The borate bioactive glass filling material may be applied to a location of a tooth having an eroded or removed enamel 35 and/or dentin layer, or having an early erosion lesion, which may be caused by chemical erosion, such as exposure to acidic compounds, beverages, or foods, or may be caused by physical abrasion, such as by filing or grinding. In one embodiment, this location to receive the borate bioactive 40 glass filling material may have exposed dentinal tubules. In another embodiment, an enamel and/or dentin layer may be removed by a physical impact against a tooth, which may result in a chipped tooth. Similarly, a physical impact may result in a cracked tooth having a fissure with exposed 45 dentinal tubules. In another embodiment, the location may be within or on a cavity or depression caused by tooth decay (i.e. dental caries). In another embodiment, the location may be located below the gum line or at a place where the gum has receded. Alternatively, the borate bioactive glass filling 50 material may be applied to a surface of a tooth that is not enamel or dentin, for example, the cementum. As nonlimiting examples, the tooth may be an incisor, a cuspid, a bicuspid, a premolar, or a molar, and may be a primary tooth or a permanent tooth. The borate bioactive glass filling 55 material may be placed by means of a dental spatula, an elevator, an applicator, or a brush, or may be applied by extruding from a tube or syringe. In one embodiment, where the borate bioactive glass filling material is applied by an applicator, it may be applied by a Microbrush applicator. In 60 one embodiment, the borate bioactive glass filling material may be applied to fill a cavity or depression on the surface of the tooth, so that the borate bioactive glass filling material lies flush against the surface of the tooth. In other embodiments, an amount of borate glass filling material may be 65 applied that is less than that required for a flush surface (thus leaving a concave surface or a surface within the tooth), or

8

the amount of borate bioactive glass filling material may be greater than that required for a flush surface (thus leaving a convex shape). The ratio of the applied volume of the borate bioactive glass filling material to the volume of the tooth above the gum line may be 1:200-1:1, preferably 1:50-1:2, more preferably 1:40-1:5. In an alternative embodiment, a single volume of borate bioactive glass filling material may not be placed just on a single tooth, but on two or more teeth as a contiguous volume, such as filling a gap between two teeth.

The bioactive borate glass filling material may potentially be used for non-dental bone structures as well. Since bones can often regenerate, materials for bone repair should be selected based on their abilities in slow degradation to components that may be used for tissue renewal and/or safe removal afterward.

Since dentin is covered in a hard outer layer of calcium phosphate mineral containing enamel, which is the hardest substance in the human body, when the enamel is cracked, chipped, or decayed, the dentin is exposed to acid and bacteria build up. While bones are mostly made of collagen, dentin is composed of 45% of mineral hydroxyapatite, 33% of organic material and 22% of water. The bioactive borate glass composition can further provide a method of treating dentin hypersensitivity comprising applying at least one surface of a tooth sample having at least one indication of dentin hypersensitivity with a formulation including any of the disclosed compositions.

In one embodiment, before applying the borate bioactive filling material, the surface of the tooth may be cleaned or prepared by air jet, water jet, polishing, brushing, drilling, scraping, grinding, acid etching, or de-mineralizing. Acid etching or de-mineralizing may be done with a solution comprising citric acid, phosphoric acid, EDTA, hydrochloric acid, acetic acid, or some other inorganic acid, organic acid, or chelating agent. In one embodiment, preparation of the surface by drilling, scraping, grinding, acid etching, or de-mineralizing may increase the surface roughness and provide additional crevices for a layer of calcium phosphate to deposit and anchor. The surface roughness on the prepared tooth, for example, within a 10 μm×10 μm region, may possess an Ra roughness value of 0.10-0.30 µm, preferably 0.12-0.25 µm. However, in some embodiments, a tooth may already have an equivalent surface roughness by erosion and may not need additional abrasion or etching.

For storage, the borate bioactive glass filling material may be formed in advance and then stored for 1-12 months, preferably 2-8 months, more preferably 3-6 months in an airtight container and stored at room temperature, or in a refrigerator or freezer. In another embodiment, a mixture of the borate bioactive glass particles, resin blend, photoinitiator and co-initiator may be formed in advance and stored. In another embodiment, each component may be prepared separately and, within 20 minutes or 10 minutes of application to a tooth, the mixture may be made to form the borate bioactive glass filling material.

Before exemplary embodiments of the present invention are described in greater detail, it is to be understood that this invention is not limited to particular embodiments described, as such may, of course, vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to be limiting, since the scope of the present invention will be limited only by the appended claims.

Where a range of values is provided, it is understood that each intervening value, to the tenth of the unit of the lower limit unless the context clearly dictates otherwise, between

the upper and lower limit of that range and any other stated or intervening value in that stated range, is encompassed within the invention. The upper and lower limits of these smaller ranges may independently be included in the smaller ranges and are also encompassed within the invention, subject to any specifically excluded limit in the stated range. Where the stated range includes one or both of the limits, ranges excluding either or both of those included limits are also included in the invention.

9

Unless defined otherwise, all technical and scientific <sup>10</sup> terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although any methods and materials similar or equivalent to those described herein can also be used in the practice or testing of the present invention, <sup>15</sup> representative illustrative methods and materials are now described.

All publications and patents cited in this specification are herein incorporated by reference as if each individual publication or patent were specifically and individually indicated to be incorporated by reference and are incorporated herein by reference to disclose and describe the methods and/or materials in connection with which the publications are cited. The citation of any publication is for its disclosure prior to the filing date and should not be construed as an admission that the present invention is not entitled to antedate such publication by virtue of prior invention. Further, the dates of publication provided may be different from the actual publication dates which may need to be independently confirmed.

It is noted that, as used herein and in the appended claims, the singular forms "a", "an", and "the" include plural referents unless the context clearly dictates otherwise. It is further noted that the claims may be drafted to exclude any optional element. As such, this statement is intended to serve 35 as antecedent basis for use of such exclusive terminology as "solely," "only" and the like in connection with the recitation of claim elements, or use of a "negative" limitation.

As will be apparent to those of skill in the art upon reading this disclosure, each of the individual embodiments <sup>40</sup> described and illustrated herein has discrete components and features which may be readily separated from or combined with the features of any of the other several embodiments without departing from the scope or spirit of the present invention. Any recited method can be carried out in the order <sup>45</sup> of events recited or in any other order which is logically possible.

The invention is further described by the following non-limiting examples which further illustrate the invention, and are not intended, nor should they be interpreted to, limit the 50 scope of the invention.

## Example

Materials and Methods

Method of Manufacturing the Borate Glass

Borate-based bioactive glass with the composition of 24.4 Na<sub>2</sub>O-26.9 CaO-2.6 P<sub>2</sub>O<sub>5</sub>-46.1 B<sub>2</sub>O<sub>3</sub> in mol % was prepared by a conventional melt-quenching method. The reagent grade Na<sub>2</sub>CO<sub>3</sub>, CaCO<sub>3</sub>, H<sub>3</sub>BO<sub>4</sub> and NaH<sub>2</sub>PO<sub>4</sub> 2H<sub>2</sub>O were 60 mixed as the glass yield of 30 g by using an aluminum mortar. The resulting mixture was put in a Pt crucible and then heated in an electric furnace in air for 1 h at 1450° C. The melt was quenched by pouring it on a stainless steel plate and pressed with another plate to obtain glass plate 65 pieces with the thickness of 0.2-1 mm Glass particles were obtained by crushing the glass using a porcelain mortar and

10

pestle. The glasses were pulverized (less than 90 micron) using agate planetary mill and were treated with g-meth-acryloxypropyltrimethoxysilane (g-MPS) (Aldrich Chemical Co., Milwaukee, Wis.) in acetone.

Synthesis of Borate Temporary Filling Material

The Borate glass was incorporated at a concentration of (50 wt %) into a co-monomers resin blend (DA) consisting of 34.75 wt % bisphenol A diglycidyl ether dimethacrylate (Bis-GMA), 15% Ethylene glycol dimethacrylate, 0.15 wt % ethyl N,N-dimethyl-4-aminobenzoate (EDMAB) (Co-initiator), and 0.1 wt % camphorquinone (CQ) (Initiator). The whole mixture was placed in opaque bottles and placed in ultrasonic bath for two minutes.

Transmicroradiography Experiment

Class V cavities were prepared on the buccal and lingual surfaces of 20 lower freshly extracted third molars. The occlusal margins of the prepared cavities were in enamel and the gingival margins located at the cemento-enamel junction. Using a cylindrical marked diamond point the cavity preparation was performed so that the dimensions were standardized, (4.0 mm in width, 3.0 mm in height, and 2 mm in depth). The buccal cavities received the ready-made temporary fillings while the lingual cavities received the borate temporary filling.

5 Simulated Caries Acidic Challenge

All teeth having the class V cavities had their surfaces masked with two layers of nail varnish leaving the cavity cavo-surface margins and cavity walls uncovered by the nail varnish. The uncovered tooth structures were challenged with buffered demineralization solution (2.2 mM CaCl<sub>2</sub>), 10 mM NaH<sub>2</sub>PO<sub>4</sub>, 50 mM acetic acid, 100 mM NaCl, 1 ppm NaF, 5 mM NaN<sub>3</sub>; pH 4.5).

Borate Glass Temporary Glass Application

The buccal cavities' demineralized walls received the ready-made temporary material while the lingual cavities received the light curing borate temporary filling followed by light curing for 30 seconds. The specimens were stored in a remineralizing solution of 1.5 mM CaCl<sub>2</sub>), 0.9 mM NaH<sub>2</sub>PO<sub>4</sub>, 0.13M KCl and 5 mM NaN<sub>3</sub> adjusted to pH 7.0 with HEPES buffer for 24 hours. The cavities were completely washed out by distilled water followed by thorough drying.

Transmicroradiography Analysis

The teeth were split vertically with an Isomet® diamond saw (Isomet® 5000; Buehler, Lake Bluff, Ill.) into buccal and lingual cavities. The cavities were dehydrated in ascending alcohol solutions), immersed in styrene monomer (2 h), and embedded in polyester resin (Rigolac, Oken, Tokyo, Japan). The cavities were filled with flowable composite and light cured for 30 seconds. The specimens were cut into sections approximately 130 to 150 µm in thickness using a low-speed diamond saw (Isomet® 5000; Buehler, Lake Bluff, Ill.) and then ground to obtain sample thicknesses ranging between 100-120 microns. TMR images were taken for the slices using an x-ray generator (CMR 2; Softex, Tokyo, Japan) at 25 kV voltage and 4 mA current for 20 min, with a Ni filter). The distance between the x-ray tube and the specimen was 15 cm. The TMR images, together with 15 aluminum step-wedges (each 15 µm in thickness), were captured in the x-ray glass plate film (High Precision Photo Plate PXHW, Konica Minolta Photo, Tokyo, Japan) and scanned as 8-bit digital images using a CCD camera (DP70, Olympus, Tokyo, Japan) attached to a microscope (BX41, Olympus). Mean mineral profiles (mineral density versus depth) were created using software. The gray values obtained after digitizing the TMR images were converted to number of the aluminum step wedges by special equations

(brightness vs. number of the step wedge), and the relative mineral density (%) was calculated as number of the step wedge in the sound (non-demineralized) area being 100%. Then the relative % was converted to vol % as the 100% in the sound area being 87 vol % [7,27,28]. The lesion depth 5 (LD, um) was defined as a distance from the lesion surface where the mineral density was 5% less than that in the sound area. The mineral loss ( $\Delta Z$ , vol. %  $\mu m$ ) was determined by the integrated mineral loss from the lesion surface to the lesion depth [21].

Spectrophotometer Experiment Results

10 anterior teeth that were freshly extracted had their surfaces masked by nail varnish leaving a treatment window of 6 mm width and 3 mm length. The created demineralized enamel region was measured by a spectrophotometer (Ray-Plicker, Limouge, France.). The Borate temporary filling material was applied onto the demineralized area once every week for 4 weeks. The specimens during the application period were stored in remineralizing solution 1.5 mM CaCl<sub>2</sub>, 20 0.9 mM NaH<sub>2</sub>PO<sub>4</sub>, 0.13M KCl and 5 mM NaN<sub>3</sub> adjusted to pH 7.0 with HEPES buffer. After the end of the re-mineralization period (30 days), the same tooth was examined again by the spectrophotometer. Results

The transmicroradiography experimental results are shown in FIGS. 1A-C. The temporary borate filling material increased the mineral content at the cervical, pulpal and occlusal walls as compared to the ready-made temporary filling material (FIG. 1A-B). Mineral loss decreased significantly p<0.05 when the borate temporary material was applied (FIG. 1C).

The spectrophotometer results (not shown) demonstrated that application of the borate temporary material once per week for four weeks improve the shade of an enamel demineralized white spot lesion from a shade of 2R15 (Vita 3D shade) to 4M1.

FIGS. 2A-B show a mechanism of the borate glass bonding treatment for dentin or enamel. The borate glass 40 Frencken J E, Peters M C, Manton D J, Leal S C, Gordan V particles embedded in the resin blend are applied to a dentin or enamel surface (FIG. 2A). Calcium and phosphate ions are then released from the borate particles and re-mineralize the dentin or enamel structures (FIG. 2B).

## CONCLUSION

The borate temporary filling material has the ability to adhere to enamel and dentin hypomineralized surfaces for at least 24 hours releasing a high amount of calcium and 50 phosphate to the demineralized enamel and dentin tissues. Previously available temporary dental filling materials are inert materials whose only function is to fill the dental cavity prepared by the dentists and prevent the impaction of food dentist. During this period (at least 24 hours and may be extended to be 10 days or more), the tooth enamel, dentin surfaces, and internal structures do not benefit from the chemical components of the temporary filling material. The presently disclosed borate temporary filling material enables the transfer of large quantities of calcium and phosphate ions from the temporary filling material to the internal structures of the enamel and dentin rendering these surfaces more resistant to caries and more suitable to receive the final resinous restorations.

The borate temporary filling material can also improve the color of the demineralized enamel white spot lesions by

12

remineralizing these enamel lesions. Previously available remineralizing materials in the market do not have this capability.

While the invention has been described in terms of its preferred embodiments, those skilled in the art will recog-

13

nize that the invention can be practiced with modification within the spirit and scope of the appended claims. Accordingly, the present invention should not be limited to the embodiments as described above, but should further include all modifications and equivalents thereof within the spirit 5 and scope of the description provided herein.

We claim:

- 1. A dental filling material comprising:
- bioactive borate glass particles, wherein the particles are at a concentration of 40-50 wt %;
- a co-monomer resin blend, wherein the bioactive borate glass particles are embedded in the co-monomer resin blend;
- a photoinitiator; and
- a co-initiator,

wherein the material does not include phosphoric acid.

- 2. The dental filling material of claim 1, wherein a composition of the particles comprises 20-30 mol % Na<sub>2</sub>O, 20-30 mol % CaO, 1-5 mol % P<sub>2</sub>O<sub>5</sub>, and 40-50 mol % B<sub>5</sub>O<sub>3</sub>.
- 3. The dental filling material of claim 1, wherein the resin 20 blend comprises 30-40 wt % bisphenol A diglycidyl ether dimethacrylate (Bis-GMA).
- **4.** The dental filling material of claim **3**, wherein the resin blend further comprises 10-20 wt % ethylene glycol dimethacrylate
- 5. The dental filling material of claim 1, wherein the dental filling material comprises 0.05-0.2 wt % camphorquinone as the photoinitiator.
- **6.** The dental filling material of claim **1**, wherein the dental filling material comprises 0.05-0.25 wt % ethyl 30 N,N-dimethyl-4-aminobenzoate (EDMAB) as the co-initiator.
- 7. The dental filling material of claim 1, wherein the bioactive borate glass particles are prepared using a melt quench synthesis method.

14

- 8. A dental filling material comprising:
- bioactive borate glass particles, wherein the particles are at a concentration of 40-50 wt % and wherein a composition of the particles comprises 20-30 mol % Na<sub>2</sub>O, 20-30 mol % CaO, 1-5 mol % P<sub>2</sub>O<sub>5</sub>, and 40-50 mol % B<sub>2</sub>O<sub>3</sub>;
- a co-monomer resin blend, wherein the bioactive borate glass particles are embedded in the co-monomer resin blend and wherein the resin blend comprises 30-40 wt % bisphenol A diglycidyl ether dimethacrylate (Bis-GMA);
- 0.05-0.2 wt % camphorquinone as a photoinitiator; and 0.05-0.25 wt % ethyl N,N-dimethyl-4-aminobenzoate (EDMAB) as a co-initiator, wherein the material does not include phosphoric acid.
- **9**. A method for applying a dental filling to a tooth structure, comprising:
  - applying the dental filling material of claim 8 onto an exposed surface of a tooth; and
  - curing with light for an effective amount of time to harden the dental filling material.
  - 10. The method of claim 9, further comprising: removing the dental filling material from the tooth; and applying a second dental filling material to the tooth.
- 11. The method of claim 10, wherein the removing step is performed 1-7 days after the curing step.
- 12. The method of claim 9, wherein the dental filling material releases calcium and phosphate ions to a hybrid layer when exposed to saliva.
- 13. The method of claim 12, wherein the calcium and phosphate ions form a hydroxyapatite layer on a surface of dentin or enamel to re-mineralize the tooth.
